Abstract

Novel magnetically separable Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ nanocomposites were fabricated by a feasible hydrothermal route. Fourier transform infrared (FT-IR) spectroscopy, X-ray diffraction (XRD), scanning electron microscopy (SEM), energy dispersive X-ray spectroscopy (EDX), transmission electron microscopy (TEM), X-ray photoelectron spectroscopy (XPS), UV-vis diffuse reflectance spectroscopy (DRS), vibrating sample magnetometer (VSM), and N$_2$ adsorption–desorption analysis were employed to examine the structure, morphology, particle size, phase composition, optical and magnetic properties of the as-synthesized nanocomposites. The results of the findings showed demonstrated the successful coupling of spherical CoFe$_2$O$_4$ nanoparticles and plate–like Bi$_2$O$_2$CO$_3$ nanostructures. The catalytic performance of magnetic Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ nanocamposites was evaluated in the reduction of some aromatic nitrocompounds such as nitrophenols and nitroanilines by using sodium borohydride (NaBH$_4$) aqueous solution at room temperature. The Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ nanocomposite with 30 %wt. CoFe$_2$O$_4$ exhibited the best performance in the reduction of aromatic nitrocompounds with 100% conversion into the corresponding amino compounds within 15–30 min with rate constant of 0.10–0.24 min$^{-1}$. The effect of catalyst dosage was also investigated on the efficiency of reduction process. Furthermore, magnetic Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ nanocomposite could be easily removed by an external magnet from the reaction system.

Keywords: Plate-like Bi$_2$O$_2$CO$_3$; bismuth-based nanomaterials; cobalt ferrite, magnetic nanocomposite; catalytic reduction; nitrophenols

1. Introduction

Nitrophenols are one of the most organic pollutants in industrial and agricultural waste waters. Nitrophenols and their derivatives are significant by-products produced from pesticides, herbicides and synthetic dyes. Among them, 4-nitrophenol (4-NP) is well known to cause damage to the central nervous system, liver, kidney and both animal and human blood. Hence its removal from the environment is a crucial task. On the other hand, the reduction of 4-NP to 4-aminophenol (4-AP) is essential in pharmaceutical industries for the manufacture of analgesic, antipyretic and other drugs, in photographic developer, corrosion inhibitor, anticorrosion lubricant, etc. Over the past few decades, the catalytic reduction of nitrophenols using NaBH$_4$ as reducing agent in aqueous medium has received considerable attention as a relatively simple and clean method. Many reports are available on the application of metal and metal oxides nanocatalysts for the reduction of nitrophenols in the presence of NaBH$_4$. However, the separation of them from the reaction mixture is an important issue. In order to solve these problems, the magnetic separable nanocomposites such as Au/Fe$_3$O$_4$, Ag@Pd satellites/Fe$_3$O$_4$, Pt/Fe$_3$O$_4$/CNTs, and Fe$_3$O$_4$/SiO$_2$/Ag have been exploited for the catalytic reduction of nitrophenols in aqueous media. In such approaches, although nanocomposites showed improved recyclability but they suffered from one or more drawbacks such as the usage of expensive noble metals and the multi-step preparation procedures. Hence, the development of an alternative inexpensive, facile and easy-removal magnetic catalyst for the reduction of nitrophenols is highly desirable in the context of environmental and industrial concerns.

During the recent years, bismuth-based nanostructured materials, such as Bi$_2$O$_3$, BiVO$_4$, Bi$_2$WO$_6$, Bi$_2$MoO$_6$, etc., have been used as heterogeneous catalysts for the reduction of 4-nitrophenol to 4-aminophenol. Bismuth-based nanomaterials have attracted a considerable interest due to their unique chemical, physical, and catalytic properties. Bismuth oxide (Bi$_2$O$_3$) is an industrially important material used for various applications such as melts, optical fibers, infrared windows, and paint pigments. Bismuth vanadate (BiVO$_4$) is a promising material for solar energy conversion due to its direct band gap of 2.7 eV and high optical transparency in the visible region. Bismuth tungstate (Bi$_2$WO$_6$) is a promising candidate for optoelectronic devices due to its high photoluminescence quantum efficiency and large photoluminescence band gap. Bismuth molybdate (Bi$_2$MoO$_6$) is a promising material for photocatalytic water splitting due to its high stability and good catalytic activity. The magnetic properties of Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ nanocomposite could be easily removed by an external magnet from the reaction system.
BiOX (X = Cl, Br, I), and so on, have received a great deal of attention due to their unique catalytic and photocatalytic activities. Among these compounds, some studies have focused on the fabrication of bismuth subcarbonate (Bi$_2$O$_2$CO$_3$) and its composites.\textsuperscript{55} Up to now, many kinds of Bi$_2$O$_2$CO$_3$-based hybrid composites such as Bi$_2$O$_2$CO$_3$/β-Bi$_2$O$_3$,\textsuperscript{36} Bi$_2$O$_2$CO$_3$/MoS$_2$,\textsuperscript{37} Bi$_2$O$_2$CO$_3$/BiOX (X = Cl, Br and I),\textsuperscript{38–40} Bi$_2$O$_2$CO$_3$/Bi$_2$WO$_6$,\textsuperscript{41} Bi$_2$O$_2$CO$_3$/Bi$_2$S$_3$,\textsuperscript{42} Bi$_2$O$_2$CO$_3$/CdS,\textsuperscript{43} Ag$_2$O/Bi$_2$O$_2$CO$_3$,\textsuperscript{46} and MWNTs/Bi$_2$O$_2$CO$_3$\textsuperscript{56} have been successfully synthesized, which showed enhanced catalytic or photocatalytic stability and activity than Bi$_2$O$_2$CO$_3$ alone. But most of these composites are difficult to separate and recycle, seriously limiting their extensive application. Therefore, fabrication of well-defined and easy separated Bi$_2$O$_2$CO$_3$-based catalysts from the suspended reaction system via a simple process remains to be a great challenge. To overcome this shortfall, coupling Bi$_2$O$_2$CO$_3$ with magnetic materials is highly desirable. In this regard, spinel-type metal ferrites (MFe$_2$O$_4$) are known to have high magnetic performance as well as excellent chemical stability.\textsuperscript{51} Among them, CoFe$_2$O$_4$ nanoparticles have a higher strong magnetic property, and therefore, CoFe$_2$O$_4$ based composites can be magnetically separable in a suspension by virtue of their own magnetic properties without any introduction of additional magnetic particles. Based on the previous studies, it can be expected that the modification of Bi$_2$O$_2$CO$_3$ with CoFe$_2$O$_4$ to form Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ nanocomposites may improve the catalytic activity and recyclability. Furthermore, their magnetic nature makes composites magnetically separable from the reaction mixture in a convenient manner. As far as we know, there is no report about CoFe$_2$O$_4$-modified Bi$_2$O$_2$CO$_3$ alone.

In this work, novel magnetically separable Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ nanocomposites with high catalytic performance were synthesized via loading various amounts of CoFe$_2$O$_4$ nanoparticles on the surface of plate-like Bi$_2$O$_2$CO$_3$ nanostructures by a hydrothermal method at 180 °C for 24 h. The structure, morphology, and optical properties of the obtained nanomaterials were characterized in detail. Then, the excellent catalytic activity of the as-prepared Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ composite nanomaterials was evaluated by the reduction of 4-nitrophenol in the presence of aqueous NaBH$_4$ solution under ambient conditions. In addition, the possible reaction mechanism was proposed based on the experimental results. This study provides a promising candidate for efficient removal of nitrophenols from water by an environment-friendly and economical approach.

### 2. Experimental

#### 2.1. Materials

Bismuth nitrate pentahydrate (Bi(NO$_3$)$_3$ 5H$_2$O, 98%), citric acid (98.5%), cobalt(II) nitrate hexahydrate (Co(NO$_3$)$_2$ 6H$_2$O, 98%), iron(III) nitrat hydrate (Fe(NO$_3$)$_3$ 9H$_2$O, 98%), sodium borohydride (NaBH$_4$, 98.5%), 2-nitrophenol (2-NP, 99%), 4-nitrophenol (4-NP, 98%), 2-nitroaniline (2-NA, 99%) and 4-nitroaniline (4-NA, 99%) were obtained from Merck chemical company. All other chemicals were of analytical grade, commercially available and used without further purification.

#### 2.2. Methods of Characterization

FT-IR spectra were recorded on a Schimadzu system FT-IR 8400S spectrophotometer in transmission mode from 4000 to 400 cm$^{-1}$ using KBr pellets. The XRD patterns of the samples were obtained on an X-ray diffractometer (Rigaku D-max C III) using Ni-filtered Cu Ka radiation ($\lambda$ = 1.5406 Å) UV-vis diffuse reflection spectroscopy (DRS) was performed on a Snico S4100 spectrophotometer over the spectral range 200–1000 nm by using BaSO$_4$ as the reference. The shapes and morphologies of samples were observed by a MIRA3 TESCAN field emission scanning electron microscope (FES-EM) equipped with a link energy-dispersive X-ray (EDX) analyzer. The particle size was determined by a CM120 transmission electron microscope (TEM) at an accelerating voltage of 80 kV. TEM samples were prepared by dropping the ethanol dispersion on a carbon coated copper grid. A PHS-1020 PHSCINNA instrument was used to measure the Brunauer-Emmett-Teller (BET) surface areas of the samples at liquid nitrogen temperature (77 K). Specific surface area calculations were made using Brunauer-Emmett-Teller (BET) method at the relative pressure ($p/p_0$) between 0.05 and 0.35. Magnetic measurements were carried out at room temperature using a vibrating sample magnetometer (VSM, Magnetic Dane-shpajon Kashan Co., Iran) with a maximum magnetic field of 10 kOe. X-ray photoelectron spectroscopy (XPS) was conducted using a thermo Scientific, ESCALAB 250Xi, Mg X-ray resource instrument. UV-vis spectra of nitro compounds during the reduction reaction in aqueous solutions were analyzed using a Cary 100 double beam spectrophotometer operated at a resolution of 2 nm with quartz cells with path length of 1 cm in the wavelength range of 200 to 600 nm.

#### 2.3. Preparation of CoFe$_2$O$_4$ Nanoparticles

CoFe$_2$O$_4$ nanoparticles were prepared by hydrothermal process. Fe(NO$_3$)$_3$ 9H$_2$O (1.72 g) and Co(NO$_3$)$_2$ 6H$_2$O (0.62 g) were dissolved in 25 mL distilled water (Co/Fe mole ratio of 1:2), and then the solution was adjusted to a pH of 12 with NaOH (6 M). After stirring for 60 min, the mixture was transferred to a 50 mL Teflon-lined stainless steel autoclave and maintained at 180 °C for 12 h before being cooled down in air. The resulting precipitate was filtered, washed with deionized water and ethanol, and dried at 60 °C for 6 h.

---

Zarringhadam and Farhadi: *Hydrothermal Synthesis of Novel Magnetic Plate-Like ...*
2.4. Preparation of Plate-Like Bi$_2$O$_2$CO$_3$ Nanoparticles

To obtain plate-like Bi$_2$O$_2$CO$_3$ nanoparticles, 2.0 mmol of bismuth nitrate pentahydrate [Bi(NO$_3$)$_3$ 5H$_2$O] was dissolved in 20 mL of HNO$_3$ aqueous solution (1 M), and then 1.5 mmol of citric acid (C$_6$H$_8$O$_7$) was added under magnetic stirring. The pH of the solution was adjusted to 6 by adding NaOH aqueous solution (2 M) under magnetic stirring. Finally, the white-colored precursor suspension was transferred into a 50 mL Teflon-lined stainless steel autoclave and heated for 24 h at 180 °C. After hydrothermal treatment, the autoclave was cooled down to room temperature naturally. The resulting precipitate was collected by centrifugation, washed with deionized water several times, and dried at 60 °C for 6 h.

2.5. Preparation of Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ Nanocomposites

To synthesize Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ nanocomposites, 2.0 mmol of Bi(NO$_3$)$_3$ 5H$_2$O was dissolved in 20 mL of HNO$_3$ (1 M), and then 1.5 mmol of citric acid (C$_6$H$_8$O$_7$) was added under magnetic stirring. The pH of the solution was adjusted to 6 by adding NaOH aqueous solution (2 M) under magnetic stirring. Then, the required amount of CoFe$_2$O$_4$ nanoparticles (30 and 45 wt%) was added to the Bi$_2$O$_2$CO$_3$ precursor suspension. After sonication for 30 min, the homogenized suspension was transferred into a 50 ml Teflon-lined stainless steel autoclave, sealed and maintained at 180 °C for 24 h. Then, the autoclave was naturally cooled down to room temperature and the resulting precipitate was separated by a magnet, washed with deionized water several times, dried at 60 °C and used for further characterization. The obtained samples with 30 and 45 wt% CoFe$_2$O$_4$ nanoparticles were denoted as Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$30% and Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$45%, respectively.

2.6. Catalytic Tests

The catalytic performance of the synthesized Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ nanocomposites in the reduction of 4-nitrophenol (4-NP) to 4-aminophenol (4-AP) was evaluated by excess aqueous NaBH$_4$ solution at room temperature. In a typical catalytic reaction, 2 mL of aqueous solution of 4-NP (0.2 mM) and 0.5 mL of freshly prepared aqueous solution of NaBH$_4$ (20 mM) were mixed together in a standard quartz cell, having 1 cm path length. The solution color turned to bright yellow rapidly. Then, 5 mg of the Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ nanocomposite was added and stirred at room temperature. The solution was quickly subjected to UV–Vis measurements; Afterward, the absorbance of the solution was in situ measured every several minutes (2 min) in the scanning range of 200–500 nm to obtain the successive change about the reaction. In order to optimized the catalyst amount, similar experiments have been carried out in the presence of various amount of the catalyst (2.5, 5, 10, 15, and 20 mg in 2.5 mL aqueous solutions) on the reduction of 4-NP. The reduction of 2-nitrophenol (2-NP) and 2-nitroaniline (2-NA) and 4-nitroaniline (4-NA) was also carried out under the same conditions. For comparison, similar experiment was performed in the presence of the pure Bi$_2$O$_2$CO$_3$ (5 mg) and CoFe$_2$O$_4$ (5 mg) catalysts. For recycling experiments, the Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ catalyst was recovered from the solution by an external magnet after completion of the reaction. The magnetically recovered catalyst was washed repeatedly with deionized water, dried at 60 °C and then employed for a new run.

3. Results and Discussion

3.1. Characterization of Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ Nanocomposites

FT-IR spectra of the as-prepared Bi$_2$O$_2$CO$_3$, CoFe$_2$O$_4$ and Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ samples are indicated in Figure 1. For pure Bi$_2$O$_2$CO$_3$ sample in Figure 1(a), the sharp peaks at ca. 1400 and 845 cm$^{-1}$ are the characteristic stretching peaks of carbonate and bismuth oxides, respectively. The IR spectrum of CoFe$_2$O$_4$ sample in Figure 1(b) shows typical bands of spinel-type cobalt ferrite. The peaks at 1558, 1392, 847, 759, 619 cm$^{-1}$ are assigned to the stretching vibration of Fe$^{3+}$-O and Fe$^{2+}$-O, while the bands at 532, 460 cm$^{-1}$ are associated with Fe-O-Fe. The presence of Bi$_2$O$_2$CO$_3$ in the nanocomposites causes the appearance of additional bands, which can be observed at 1400, 1386, 845 cm$^{-1}$.

Figure 1. FT-IR spectra of (a) Bi$_2$O$_2$CO$_3$, (b) CoFe$_2$O$_4$ (c) Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$30%, and (d Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$45%.
and bending vibrations of CO$_3^{2-}$ groups, respectively. Meanwhile, the intensive peak at about 550 cm$^{-1}$ was attributed to the stretching vibration of the Bi-O, suggesting the formation of Bi$_2$O$_2$CO$_3$. In the case of CoFe$_2$O$_4$ (Figure 1(b)), the two peaks appeared at 603 and 458 cm$^{-1}$ are related to the stretching vibrations of M-O bonds in the tetrahedral and octahedral sites of spinel-type oxide, respectively. FT-IR spectra of the Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ nanocomposites in Figures 1(c) and (d) show the stretching and bending vibrations correspond to the carbonate group (CO$_3^{2-}$) in Bi$_2$O$_2$CO$_3$ at 1400 and 844 cm$^{-1}$, besides strong bands of CoFe$_2$O$_4$ in the 400–600 cm$^{-1}$ range. This finding demonstrates the coexistence of Bi$_2$O$_2$CO$_3$ and CoFe$_2$O$_4$ in the nanocomposites.

The crystal structure of samples was further characterized using XRD. Figure 2 shows the XRD patterns of the Bi$_2$O$_2$CO$_3$, CoFe$_2$O$_4$ and Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ nanocomposites with different contents of CoFe$_2$O$_4$. The patterns of Figures 2(a) and (b) are well consistent with the tetragonal Bi$_2$O$_2$CO$_3$ phase (JCPDS no. 41–1488) and the spinel-type CoFe$_2$O$_4$ phase (JCPDS no. 01–1121). As shown in Figures 2(c) and (d), all the Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ samples exhibit a coexistence of both Bi$_2$O$_2$CO$_3$ and CoFe$_2$O$_4$ phases without any impurity phase, indicating successful synthesis of nanocomposites. In addition, the intensity of characteristic CoFe$_2$O$_4$ peaks at 2θ = 35.76 and 63.13 in nanocomposite increased with increasing CoFe$_2$O$_4$ amount. Besides, the diffraction peaks of Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ nanocomposites exhibited sharp and intense state, indicating a promising crystalline nature which was beneficial for the following catalytic activity.

The shape and morphology of the as-synthesized CoFe$_2$O$_4$, Bi$_2$O$_2$CO$_3$, and Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ samples were investigated by FE-SEM. The SEM images of CoFe$_2$O$_4$ sample in Figures 3(a) and (b) show a large quantity of nearly uniform monodispersed spheres with an average diameter of about 15 nm. The SEM images in Figures 3(c) and (d) show that the bare Bi$_2$O$_2$CO$_3$ sample was formed from plate-like particles which were loosely aggregated. As can be observed, the porous structure was formed by self-assembly of these nanoplates. SEM images of the Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ nanocomposites containing 30% and 45% of CoFe$_2$O$_4$ are shown in Figures 3(e) and (f), respectively. It is evident that the shape and morphology of Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ nanocomposites are similar to those of the pure Bi$_2$O$_2$CO$_3$, but many spherical CoFe$_2$O$_4$ nanoparticles are seen on the surface of plate-like Bi$_2$O$_2$CO$_3$ nanostuctures. From images, it can be clearly seen that a lot of

**Figure 2.** XRD patterns of (a) Bi$_2$O$_2$CO$_3$, (b) CoFe$_2$O$_4$, (c) Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$30%, and (d) Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$45%.

**Figure 3.** SEM images of (a and b) CoFe$_2$O$_4$, (c and d) Bi$_2$O$_2$CO$_3$, (e) Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$30% (f) Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$45% samples.
spherical \( \text{CoFe}_2\text{O}_4 \) nanoparticles with a size of about 15–20 nm were well deposited on the \( \text{Bi}_2\text{O}_2\text{CO}_3 \) nanoplates.

The size and microstructure of the as-prepared \( \text{Bi}_2\text{O}_2\text{CO}_3/\text{CoFe}_2\text{O}_4 \) samples were further investigated by TEM. The sample powder was sonicated in ethanol for 30 min and a drop of the suspension was dried on a carbon-coated microgrid for TEM measurements. The TEM images in Figure 4(a)-(c) show that the obtained \( \text{Bi}_2\text{O}_2\text{CO}_3/\text{CoFe}_2\text{O}_4 \)30% nanocomposite was formed mainly from plate-like particles with a weak agglomeration. Also, from the TEM images in Figure 4(d), it is clear that the \( \text{Bi}_2\text{O}_2\text{CO}_3/\text{CoFe}_2\text{O}_4 \)45% consists of plate-like structure with the lengths of 15–40 nm and thicknesses of several nanometers while \( \text{CoFe}_2\text{O}_4 \) nanoparticles show sphere-like shapes. It is obvious from the TEM images that the nanoplates exhibit mostly square-like shapes, although some are rectangular. As can be observed on all images, many spherical \( \text{CoFe}_2\text{O}_4 \) dark-color particles are observed to be deposited on the surface of bright plates of the \( \text{Bi}_2\text{O}_2\text{CO}_3 \). The average size of \( \text{CoFe}_2\text{O}_4 \) particles was calculated to be 15 nm from the measurements on the TEM micrographs which is in close agreement with the size obtained from XRD analysis. It is clear from the images, the morphology of the \( \text{Bi}_2\text{O}_2\text{CO}_3/\text{CoFe}_2\text{O}_4 \) composites from TEM images agreed with the SEM results.

The energy dispersive X-ray spectroscopy (EDX) was used to characterize the elemental composition of the as-prepared samples. The EDX spectra of \( \text{CoFe}_2\text{O}_4 \), \( \text{Bi}_2\text{O}_2\text{CO}_3 \) and \( \text{Bi}_2\text{O}_2\text{CO}_3/\text{CoFe}_2\text{O}_4 \)30% are shown in Figure 5. The EDX spectrum of \( \text{CoFe}_2\text{O}_4 \) in Figure 5(a) shows the existence of Co, Fe and O elements as well as the EDX spectrum of \( \text{Bi}_2\text{O}_2\text{CO}_3 \) (Figure 5(b)) shows the existence of Bi, C and O elements. In addition, the constituents of \( \text{Bi}_2\text{O}_2\text{CO}_3/\text{CoFe}_2\text{O}_4 \)30% were studied by EDX method. As shown in Figure 5(c), the EDX elemental spectrum of the nanocomposite sample exhibits elemental peaks corresponding to both \( \text{CoFe}_2\text{O}_4 \) and \( \text{Bi}_2\text{O}_2\text{CO}_3 \) and no other impure peaks can be observed, indicating that the composite sample is consisted of \( \text{CoFe}_2\text{O}_4 \) and \( \text{Bi}_2\text{O}_2\text{CO}_3 \). In all samples, the presence of Au peak at 2.2 KeV is due to SEM-EDX sample holder.

To further determine the composition and element distributions of \( \text{Bi}_2\text{O}_2\text{CO}_3/\text{CoFe}_2\text{O}_4 \)30% composite, EDX mapping measurements were also carried out. Figure 6 shows a representative SEM image of the nanocomposite with corresponding EDX elemental mappings. From the maps in Figure 6(b)-(f), can be observed that the Bi, C, O, Co and Fe elements are uniformly distributed over the sample, confirming the homogeneity of the nanocomposite. The EDX elemental mappings of the \( \text{Bi}_2\text{O}_2\text{CO}_3/\text{CoFe}_2\text{O}_4 \)30% composite (Figures 6(e) and (f)) display that the elements of Co and Fe from \( \text{CoFe}_2\text{O}_4 \) phase are distributed on the surface of the \( \text{Bi}_2\text{O}_2\text{CO}_3 \). The EDX mappings results further indicate that the \( \text{Bi}_2\text{O}_2\text{CO}_3/\text{CoFe}_2\text{O}_4 \) nanocomposites have been successfully synthesized.

The optical properties of the as-prepared \( \text{Bi}_2\text{O}_2\text{CO}_3 \), \( \text{CoFe}_2\text{O}_4 \) and \( \text{Bi}_2\text{O}_2\text{CO}_3/\text{CoFe}_2\text{O}_4 \) composites were investigated by the diffuse reflectance UV-vis spectra (DRS) absorption spectroscopy (Figure 7). Figure 7(a) displays the UV-vis diffuse reflectance spectra of the bare \( \text{Bi}_2\text{O}_2\text{CO}_3 \) (curve i), \( \text{Bi}_2\text{O}_2\text{CO}_3/\text{CoFe}_2\text{O}_4 \)30% composite (curve ii) and \( \text{CoFe}_2\text{O}_4 \) (curve iii). Bare \( \text{Bi}_2\text{O}_2\text{CO}_3 \) shows absorption edge at ~400 nm whereas pure \( \text{CoFe}_2\text{O}_4 \) shows good absorbance in the visible light region up to 490 nm. As can be
seen in curve ii of Figure 7(a), the UV-vis band of Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ nanocomposite indicates an enhancement in absorption intensity in the visible region together with a red shift, compared to that of the pure Bi$_2$O$_2$CO$_3$ due to the coupling with CoFe$_2$O$_4$ phase. The band gaps (Egs) of these three samples were calculated by the following formula based on the DRS results:\(^{57}\)

$$(\alpha h\nu)^{1/2} = B(h\nu - E_g)$$ \hspace{1cm} (1)

Where $\alpha$, $h$, $\nu$ and $B$ are absorption coefficient, plank constant, light frequency, and a constant, respectively. Therefore, Eg value of the samples can be estimated from a plot $(\alpha h\nu)^{1/2}$ versus photon energy $(h\nu)$. The intercept of the tangent to the x axis would give an approximation of the band-gap energy of the samples (Figure 7(b)). As shown in Figure 7(b) (curves i-iii), the Eg values of pure Bi$_2$O$_2$CO$_3$, Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$30% nanocomposite and pure CoFe$_2$O$_4$ were found to be 3.49, 2.89 and 2.79 eV, respectively. It is clear that the Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$30% composite shows a band gaps at 2.89 eV with a red shift compared to that of the pure Bi$_2$O$_2$CO$_3$ (3.49 eV), indicating formation of hybrid heterostructures.

The elemental composition and oxidation states of Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$30% sample were carefully analyzed by XPS. The full XPS spectrum in Figure 8(a) shows that the
sample consists of Bi, O, C, Co and Fe elements, in consistent with the EDX results. In order to further investigate the chemical state of each element, the high-resolution XPS spectra of Bi 4f, C 1s, O 1s, Co 2p and Fe 2p for the as-prepared Bi2O2CO3/CoFe2O4 30% are separately shown in Figure 8(b)-(e). As shown in Figure 8(b), the peaks located at binding energies of 159.08 and 164.39 eV are attributed to Bi 4f7/2 and Bi 4f5/2, respectively, indicating the existence of Bi3+ ions in the sample.58 In Figure 8(c), the peak at 284.78 eV is attributed to carbon reference, while the peak at 288.73 eV corresponds to the carbon of carbonate ion (CO32−) in Bi2O2CO3.58 For the oxygen element (Figure 8(d)), the O 1s peaks are well fitted into three different peaks at 529.73 eV, 530.68 eV and 532 eV. According to the experiment results, the peak located at 529.73 eV is arisen from Bi-O in Bi2O2CO3 while that at 530.63 eV is from CO32− species and CoFe2O4.59 Other small peak at higher binding energy of 532 eV can be attributed to the presence of surface-chemisorbed adsorbed H2O.60 As shown in Figure 8(e), the peaks at 979.91 eV and 795.67 eV could be assigned to Co 2p3/2 and Co 2p1/2, respectively, shoudering with satellite peaks at 785.29 eV and 802.27 eV. Figure 8(f) shows Fe 2p peaks at binding energies of 710.35 eV (Fe 2p3/2) and 724.24 eV (Fe 2p1/2) with weak satellite peaks at 718.50 eV and 733.04 eV. The observed Co 2p and Fe 2p photoelectron peaks are consistent with those reported for Co2+ and Fe3+ in CoFe2O4.61 The above results can powerfully support the presence of CoFe2O4 in the as-prepared Bi2O2CO3/CoFe2O4 sample, implying the formation of heterojunction between CoFe2O4 and Bi2O2CO3 in the resulted composite.

The BET surface area and porous structure of the Bi2O2CO3/CoFe2O4 composite were investigated based on nitrogen adsorption–desorption. Figure 9 gives the adsorption–desorption isotherms and the corresponding pore size distribution curve of the Bi2O2CO3/CoFe2O4 30% sample. As observed in Figure 9, the sample shows a type-III isotherm according to the IUPAC classification.62 The isotherm shows a distinct H3 hysteresis loop in the relatively high pressure range (p/p0 = 0.8–1). Generally, it is believed that the H3 hysteresis loop is related to the mesopores through the aggregates of plate-like particles which were further observed from the corresponding pore size distribution curve in the inset of Figure 9.63 The obtained BET specific surface area of the Bi2O2CO3/CoFe2O4 30% sample is 88.09 m2 g−1, whereas that of the Bi2O2CO3 sample is 8.7 m2 g−1.63 Accordingly, it is clear that the BET surface area of the Bi2O2CO3/CoFe2O4 30% catalyst is much larger (about 10 times) than that of pure Bi2O2CO3. The increased surface area may be also beneficial for the increase of active sites and catalytic activities. The total pore volume is 0.297 cm3/g and the average pore size of this sample is 1.27 nm, which is estimated using the Barrett–Joyner–Halenda (BJH) method from the ad-
The sorption branch of the N$_2$ isotherm as shown in the inset of Figure 9.

Figure 10 shows the magnetization measurement for the as-prepared Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ nanocomposites and pure CoFe$_2$O$_4$, using a vibrating sample magnetometer (VSM) at room temperature. The magnetization curves of the nanocomposites undoubtedly indicate ferromagnetism orders due to the presence of ferromagnetic CoFe$_2$O$_4$ nanoparticles. The saturation magnetization values of Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$30%, Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$45% and pure CoFe$_2$O$_4$ were found to be 17.15, 28.68 and 63.36 emu/g, respectively. The saturation magnetizations of the magnetic nanocomposites decrease compared with that of pure CoFe$_2$O$_4$, which can be attributed to the nano-magnetic Bi$_2$O$_2$CO$_3$ component. As demonstrated in the inset of Figure 10, complete separation of the catalyst colloids from the solution can be achieved under an external magnetic field. The rapid and easy magnetically separation of hybrid from water will assure the effective collection of the used catalysts and avoid the loss of nanoparticles for environmental risks.

3.2. Catalytic Reduction of 4-Nitrophenol

To investigate the catalytic activity of Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ nanostructures with different contents of CoFe$_2$O$_4$, the reduction of 4-nitrophenol (4-NP) to 4-aminophenol (4-AP) by excess NaBH$_4$ in aqueous solution was used as the model reaction (Figure 11). Usually, 4-NP solution exhibits a strong absorption peak at 317 nm and a weak shoulder peak at 400 nm in the region of 250–550 nm. After alkali NaBH$_4$ is added into 4-NP solution, the absorption peak at 317 nm disappears; only the one at 400 nm exists and markedly increases, which should be attributed to the production of the intermediate state, 4-nitrophenolate ion. The intermediate can stably exist for a couple of day still a catalyst is introduced into the above system. Here, the peak at 400 nm gradually decreases, and concomitantly, a new peak at 305 nm appears due to the production of 4-AP. Figure 11(a) exhibits the UV–vis absorption spectra of the 4-NP-NaBH$_4$-H$_2$O system after reacting for various durations in the presence of 5 mg pure Bi$_2$O$_2$CO$_3$ nanostructures. One can easily find that the peak intensity at 400 nm markedly decreases with the prolonging of the reaction time and disappeared after 32 min. However, Bi$_2$O$_2$CO$_3$ nanostructures with different contents of CoFe$_2$O$_4$ exhibit different catalytic activities for the reduction of 4-NP. As shown in Figure 11(b), it merely took 20 min to completely convert 4-NP to 4-AP in the presence of Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$30% nanocomposite. After the same amount of Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$45% was used as the catalyst, it took 60 min to complete the reaction (Figure 11(c)). Namely, among various samples, Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$30% bears the strongest catalytic activity. Introduction of CoFe$_2$O$_4$ in the composite significantly improves the catalytic activities of Bi$_2$O$_2$CO$_3$. However, an excess addition of CoFe$_2$O$_4$ showed decrease in catalytic efficiencies. In the present work, the reduction reaction of 4-NP to 4-AP could be reasonably assumed as a pseudo-first-order kinetics with regard to 4-NP owing to the presence of excess NaBH$_4$. This pseudo-first-order kinetics equation can be described as ln(C$_0$/C$_t$) = kt. Here, C$_0$ and C$_t$ represent the initial and instantaneous concentrations of 4-NP, respectively; and k and t stand for the apparent rate constant and the reaction time in turn. The apparent rate constant values were calculated from the slope of plot of ln(C$_0$/C$_t$) versus reaction time (Figure 11(d)). The apparent rate constant (k) value for the Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$30% sample (0.20 min$^{-1}$) was estimated which is higher than Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$45% (0.04 min$^{-1}$) and pure Bi$_2$O$_2$CO$_3$ (0.13 min$^{-1}$) samples. From the observed results, it was ev-
ident that the catalytic activity deteriorates with increasing CoFe$_2$O$_4$ content, showing that the loading percentage and intimate contact between two materials play an important role in determining catalytic efficiency. This means that with higher content of CoFe$_2$O$_4$ the number of the active catalytic reaction sites decreases and cause a negative influence on the catalytic processes. Excessive amount of

**Figure 11.** UV-vis spectral changes during the reduction of 4-NP with NaBH$_4$ over different catalysts: (a) pure Bi$_2$O$_2$CO$_3$, (b) Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$30%, (c) Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$45% and (d) Plot of ln($C_0/C$) against the reaction time (the inset is the apparent rate constant values). Conditions: 4-NP (2 mL, 0.2 mM), catalyst (5.0 mg), NaBH$_4$ (0.5 mL, 20 mM), at 25 °C.

**Figure 12** (a) Plot of ln($C_0/C$) against the reaction time in the presence of different amounts of Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$30% catalyst, and (b) the apparent rate constant values). Conditions: nitro compounds (2 mL, 0.2 mM) and NaBH$_4$ (0.5 mL, 20 mM), at 25 °C were used in all reactions.
CoFe\textsubscript{2}O\textsubscript{4} may cover the active sites at the surface of Bi\textsubscript{2}O\textsubscript{2}CO\textsubscript{3} and also could hinder the contact with 4-NP. The highest catalytic performance of Bi\textsubscript{2}O\textsubscript{2}CO\textsubscript{3}/CoFe\textsubscript{2}O\textsubscript{4}30% composite can be attributed to intimate contact between Bi\textsubscript{2}O\textsubscript{2}CO\textsubscript{3} and CoFe\textsubscript{2}O\textsubscript{4} which facilitates the electron transfer. Moreover, the existence of CoFe\textsubscript{2}O\textsubscript{4} in composites makes them magnetically separable during catalytic reactions.

The effect of the catalyst amount on the catalytic efficiency was investigated as well. Figure 12(a) shows linear relationships between ln(C\textsubscript{0}/C\textsubscript{t}) and the reaction time in the presence of different amounts of Bi\textsubscript{2}O\textsubscript{2}CO\textsubscript{3}/CoFe\textsubscript{2}O\textsubscript{4}30% nanostructure. As shown in Figure 12(b), the rate constants (k\textsubscript{app}) of 4-NP reduction reaction were calculated to be 0.04, 0.20, 0.63 and 0.66 min\textsuperscript{-1} from the slope of the straight with various amount of Bi\textsubscript{2}O\textsubscript{2}CO\textsubscript{3}/CoFe\textsubscript{2}O\textsubscript{4}30% catalyst. The k\textsubscript{app} increased as the amount of Bi\textsubscript{2}O\textsubscript{2}CO\textsubscript{3}/CoFe\textsubscript{2}O\textsubscript{4}30% catalyst increasing from 2.5 to 20 mg. A higher dosage of Bi\textsubscript{2}O\textsubscript{2}CO\textsubscript{3}/CoFe\textsubscript{2}O\textsubscript{4}30% nanocomposite in the solution provides more active sites for the generation of H\textsubscript{2} and e\textsuperscript{-} (from NaBH\textsubscript{4}), led to an increased reaction rate.

Furthermore, it was found that the present catalyst could also catalyze the reduction of other aromatic nitrocompounds including 4-nitroaniline (4-NA), 2-nitroaniline (2-NA) and 2-nitrophenol (2-NP), to corresponding amines. Figure 13(a)-(c) shows the reduction of three nitroarene by NaBH\textsubscript{4} in the presence of Bi\textsubscript{2}O\textsubscript{2}CO\textsubscript{3}/CoFe\textsubscript{2}O\textsubscript{4}30% nanocomposite. The reductive reactions were completed within 15 min (for 4-NA), 29 min (for 2-NA) and 16 min (for 2-NP), respectively. The calculated reaction rate constants (k\textsubscript{app}) for these substrates are displayed in Fig. 13(d). The k\textsubscript{app} values of these substrates are as the following order: 4-NA (0.24 min\textsuperscript{-1}) > 2-NP (0.23 min\textsuperscript{-1}) >2-NA (0.1 min\textsuperscript{-1}). Since the reactions were carried out under the same experimental conditions, the different rates can be related to the structures of nitrocompounds.

In addition to catalytic activity, the stability and reusability of catalysts are important issues for their practical applications. The stability of as synthesized Bi\textsubscript{2}O\textsubscript{2}CO\textsubscript{3}/...
CoFe₂O₄ 30% catalyst was checked by performing four consecutive cycles. The catalyst used in any experiment was collected by external magnetic field, washed with distilled water, dried at 60 °C and then employed for a new run without any observable weight loss. As shown in Figure 14, no significant loss of the catalytic activity can be observed after five successive runs of 4-NP reduction, indicating that the present composite catalysts are stable enough during the repeated experiments.

The nature of the recovered catalyst was also tested. As shown in Figure 15 (a) and (b), XRD pattern and FT-IR spectrum of the recycled Bi₂O₂CO₃/CoFe₂O₄30% nanocomposite catalyst did not show significant changes after the fourth run in comparison with the fresh catalyst (see Figures 1(c) and 2(c)). Figures 15(c) and (d) show the SEM and TEM images of the catalyst after five cycles, respectively. It could be observed that the recovered catalyst kept its initial size and morphology (see Figures 3(e)-(f) and 4) and the surface of Bi₂O₂CO₃ nanoplates was still decorated with CoFe₂O₄ nanoparticles, revealing the strong binding

**Figure 14.** Recyclability of the of Bi₂O₂CO₃/CoFe₂O₄30% nanocomposite in the reduction of 4-NP. Conditions: catalyst (5.0 mg), [4-NP] = 0.2 mM and [NaBH₄] = 20 mM, at 25 °C.

**Figure 15.** (a) XRD pattern, (b) FT-IR spectrum, (c) SEM image, and (d) TEM image of the recovered Bi₂O₂CO₃/CoFe₂O₄30% nanocomposite after the 5th run.
between the CoFe$_2$O$_4$ nanoparticles and Bi$_2$O$_2$CO$_3$ nanoplates. Therefore, the as-prepared Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ composites can work as an effective catalyst for the re-
duction nitroaromatic compounds with good stability and recyclability.

In order to show the advantage of the present method, we have compared the obtained results in the redu-
tion of 4-NP with NaBH$_4$ catalyzed by Bi$_2$O$_2$CO$_3$/
CoFe$_2$O$_4$30% with some reported catalysts in the litera-
ture. From Table 1, it is clear that with respect to the re-
action conditions and/or reaction times, the present 
method is more suitable and/or superior. It is clear that 
reaction in the presence of most reported catalysts re-
quired longer reaction times (Table 1, entries 1–10).

However, the present catalyst showed close or lower cata-
lytic activity compared with some of the catalysts (Table 
1, entries 11 and 12). Also, the results confirms that this 
magnetic catalyst has higher catalytic activity than that of 
the previously reported Bi$_2$O$_2$CO$_3$/NiFe$_2$O$_4$30% catalyst 
in the reduction of 4-nitrophenol to 4-aminophenol un-
der same conditions (Table 1, entries 13 and 14). Fur-
thermore, the present nanocomposite can be easily pre-
pared in one-step without the use of harsh, toxic and 
expensive chemicals which is very important in practical 
applications.

**4. Conclusions**

To conclude, a series of novel plate–like Bi$_2$O$_2$CO$_3$/
CoFe$_2$O$_4$ magnetic nanocomposites were successfully 
synthesized via a simple hydrothermal method for the 
first time and applied to catalyze the reduction of nitro-
arenes. Compared with the individual Bi$_2$O$_2$CO$_3$ and 
CoFe$_2$O$_4$, the composite catalysts exhibit higher catalytic 
performance and stability for 4-nitrophenol reduction under ambient conditions. Compared with those noble 
metals such as Au, Ag, Pt and Pd, Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ 
composites were easy to available and inexpensive. The 
preparation procedure of Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ magnetic 
nanocomposites via hydrothermal method was simple.

And the as-prepared Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ magnetic nano-
composites were stable and well-dispersed. Moreover, 
the prepared Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ nanocomposites were 
magnetically separable from water with higher long-time 
use stability. This study provides a new approach for re-
ducing and removing nitroarenes pollutants (e.g. 4-NP) 
in wastewater without introducing secondary pollutant into the system. Studies on the synthesis of nanocompos-
ites of Bi$_2$O$_2$CO$_3$ with other ferrites (MFe$_2$O$_4$; M = Ni, Zn, 
Cu, Mn, …) and their thermal catalytic and photocatalyt-
ic applications are currently in progress and underway in 
our laboratory.

Povzetek
Nove magnetne nanodele Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ smo pripravili s hidrotermalno sintezo. Infracrveno spektroskopijo (FT-IR), rentgensko difracijo (XRD), vrstično elektronsko mikroskopijo (SEM), enerjijsko disperznino spektroskopijo (EDX) in s magnetometrom z vibrirajočim vzorcem (VSM). Nanodele Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ smo ocenili s redukcijo nekaterih aromatičnih nitro-spojin, kot so nitrofenoli in nitroanilini. Prispevek nam je omogočil raziskovanje katalitične aktivnosti magnetnih nanokompozitov Bi$_2$O$_2$CO$_3$/CoFe$_2$O$_4$ v katalitični redukciji nitrospojov.
